Magnetophononics: ultrafast spin control through the lattice

Dr. Michael Fechner

MPSD Hamburg

The interplay of the electronic and crystal structure determines the functional properties of materials. Consequently, a temporal intervention into this interaction possibly alters existing properties or create transient new ones, which non-existed previously. Here I present: How one can use the selective excitation of phonons, elementary stimuli of the crystal lattice, as a perturbative method to manipulate the magnetic properties of insulators. I will first introduce the general theoretical concept of phonon excitation towards the non-linear regime, also known as non-linear phononics [1], and its possible side effects onto crystal and electronic structure. In the following, I will discuss in detail two studies which utilize this approach in magnetic materials. The first example is the temporal light-induced modulation of the electric polarisation, which creates a magnetization even in materials with no existing spin structure. This transient state of broken space and partly odd symmetry is multiferroic and comprises unexpected outcomes like a phonon Zeeman effect [2] and magnon excitation [3]. In the second example [4], I show how the phonon excitation and its related structural distortion modulates magnetic exchange interactions. For the specific case of Cr₂O₃, the right tuning of induced distortions allow modulating the magnetic spin arrangement, which generates a new magnetic state. At the end of my talk will give an outlook and my perspective on future developments in this field.
